

CH 16 PROBABILITY MODELS GUIDE

Bernoulli Trials – binary trials that measure the outcome

Conditions to be a Bernoulli Trial:

- 1) Two possible outcomes (success and failure)
- 2) Probability of success is constant (same chance every time)
- 3) Trials are independent

10% Condition – exception to 3rd condition of Bernoulli Trials

- If trials are not independent (sampling without replacement), then it is ok to proceed with Bernoulli Trials as long as the random sample is smaller than 10% of the population.

Geometric Probability Models – Used to model the probability of an event until the first success occurs

(order matters)

Notation: Geom(p)

- Means the probability of success (p) for a geometric probability model

| Variables | Formulas | Purpose of Formula |
|---|--------------------------------|---|
| p = probability of success | $P(X = x) = q^{x-1}p$ | Probability of Geometric Event |
| q = probability of failure $q = 1 - p$ (complement rule) | $E(X) = \frac{1}{p}$ | Expected Value (mean/center) of Geometric Event |
| X = number of trials until 1 st success | $SD(X) = \sqrt{\frac{q}{p^2}}$ | Standard Deviation (spread) of Geometric Event |

Calculator TI-83 and 84

Under 2ND DISTR button, use the following to help you:

p = defines the probability of the model (success)

x = number of trials UNTIL success

| Button | Purpose | Meaning |
|---------------|---|------------------------------|
| Geompdf(p, x) | Probability of Individual Outcome (1 Event) | Probability Density Function |
| Geomcdf(p, x) | Probability of several outcomes (sum) -When the success (event) can happen on or before the last trial | Cumulative Density Function |

Binomial Probability Models – chance of an overall outcome, regardless of the order it occurs

(# of successes in specified # of trials - Binom(n,p) is the notation)

| Variables | Formulas | Purpose of Formula |
|------------------------------|-----------------------------------|--|
| p = probability of success | $P(X = x) = {}_n C_x p^x q^{n-x}$ | Probability of Binomial Event |
| q = probability of failure | ${}_n C_x = \frac{n!}{x!(n-x)!}$ | X successes in n trials |
| X = number of successes | $E(X) = np$ | Expected Value (mean/center) of Binomial Event |
| n = number of trials | $SD(X) = \sqrt{npq}$ | Standard Deviation (spread) of Binomial Event |

Calculator TI-83 and 84

Under 2ND DISTR button, use the following to help you:

| Button | Purpose | Meaning |
|-----------------|--|------------------------------|
| Binompdf(n,p,x) | Probability of Individual Outcome (1 Event from number of trials) | Probability Density Function |
| Binomcdf(n,p,x) | Probability of several outcomes (sum) -Total successes x or fewer based on number of trials | Cumulative Density Function |

Success/Failure Condition: binomial model is approximately Normal if we expect at least 10 successes and 10 failures.

| | | |
|--------|--------------|--------------|
| Means: | $np \geq 10$ | $nq \geq 10$ |
|--------|--------------|--------------|

- Tips:**
- Use your calculator to find most answers
 - Check your conditions to see if something applies
 - Geometric and Binomial are different
 - *Geometric* – probability of when first success occurs (order matters)
 - *Binomial* – probability of any successes within the set amount of trials (order doesn't matter)
 - Use the Normal Model if the success/failure condition applies to continuous random variables to find the chance of the event

Example Diagram of Bernoulli Trials
